

Java Variables

Description

- ✱ Variable is the name of the kept back region allotted in memory. It can declare based on [any Primitive or Reference types](#) prescribed by Java language.
- ✱ **Syntax** for Variable declaration is:

```
Data type variable\_name [=value];
```
- ✱ More than a [single variable](#) can be declared for the [same data type](#), in the [same line](#).
- ✱ When a variable is declared, the computer allocates memory block, named by that variable, according to the variable's data type.
- ✱ This block is stored with the value of that variable.

Types of variables:

1. Local variables
 2. Instance variables
 3. Static variables

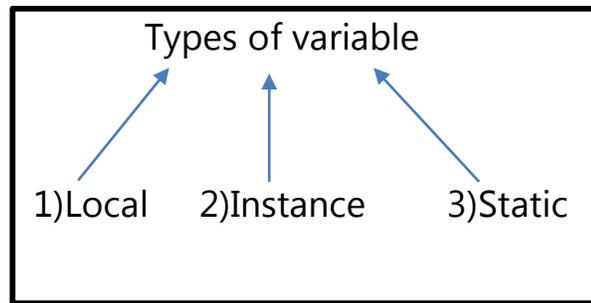

Fig1. Variable Types

Local Variable:

- ⌘ Declared [inside the method / constructor](#).
- ⌘ Holds life till the survival of that [particular method / constructor](#).
- ⌘ Cannot be accessed [outside of its method / constructor](#).
- ⌘ Must be allotted a value soon after its declaration.
- ⌘ Memory allocations are executed [inside the stack](#).
- ⌘ Access modifiers are not [applicable due](#) to its limited scope.

Instance Variable:

- ⌘ Declared [outside](#) the method but [inside the class](#).
- ⌘ Created when an object is formed using '[new](#)' [keyword](#) and shattered when the object is destroyed.
- ⌘ Can be [referenced anywhere all over](#) the class.
- ⌘ Memory allocations are executed in the heap.
- ⌘ Free to be declared before or after its usage.
- ⌘ Access [modifiers](#) are applicable.
- ⌘ Has a [default value](#) as null.

- ⌘ Called by name at the place of access in [non-static methods](#).
- ⌘ Called by fully qualified name like [ObjectReferenceName.InstanceVariableName](#) within static methods.

Static variable:

- ⌘ Declared with the [static keyword](#) inside the class, but inside a method.
- ⌘ Created when the program execution starts and shattered when the [program execution ends](#).
- ⌘ Seldom used.
- ⌘ Always declared as [constant](#) and hence [never](#) have a [change](#) in its [value](#).
- ⌘ Can be [referenced anywhere](#) all over the class, [similar to instance variable](#).
- ⌘ Memory allocations are executed in [static memory](#).
- ⌘ Access modifiers such as [public / private](#) and final are applicable.
- ⌘ Default values are allotted [as per the variable type](#).
- ⌘ Accessed by the user using [ClassName.VariableName](#).

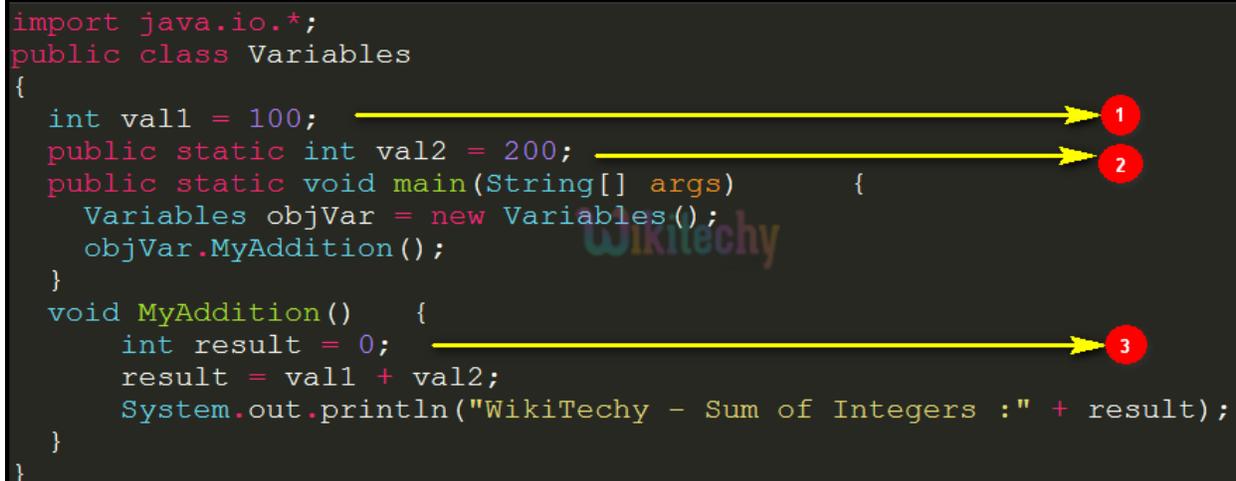

Sample Code:

```
import java.io.*;
public class Variables
{
    int val1 = 100;
    public static int val2 = 200;
    public static void main(String[] args)
    {
        Variables objVar = new Variables();
        objVar.MyAddition();
    }
    void MyAddition()
    {
        int result = 0;
        result = val1 + val2;
        System.out.println("WikiTechy - Sum of Integers :" + result);
    }
}
```

Code Explanation:

```
import java.io.*;
public class Variables
{
    int val1 = 100;
    public static int val2 = 200;
    public static void main(String[] args)
    {
        Variables objVar = new Variables();
        objVar.MyAddition();
    }
    void MyAddition()
    {
        int result = 0;
        result = val1 + val2;
        System.out.println("WikiTechy - Sum of Integers :" + result);
    }
}
```

- 1 Instance Variable – has life all over the class "Variables".
- 2 Static Variable – has life all over the class "Variables".
- 3 Local Variable – has life within the method "MyAddition()".

Sample Code:

```
import java.io.*;
public class Variables
{
    int val1 = 100;
    public static int val2 = 200;
    public static void main(String[] args)    {
        Variables objVar = new Variables();
        objVar.MyAddition();
    }
    void MyAddition()    {
        int result = 0;
        result = val1 + val2;
        System.out.println("WikiTechy - Sum of Integers :" + result);
    }
}
```

Output

```
Administrator: Command Prompt
C:\Program Files\Java\jdk1.8.0_66\bin>javac Variables.java
C:\Program Files\Java\jdk1.8.0_66\bin>java Variables
WikiTechy - Sum of Integers :300
C:\Program Files\Java\jdk1.8.0_66\bin>
```

✿ Hence the java variables execution has been done successfully.
